Bayes' theorem converts the results from your test into the real probability of the event. For example, you can: Correct for measurement errors. If you know the real probabilities and the chance of a false positive and false negative, you can correct for measurement errors. Relate the actual probability to the measured test probability.

Bayes theorem is what allows us to go from a sampling (or likelihood) distribution and a prior distribution to a posterior distribution. What is a Sampling Distribution? A sampling distribution is the probability of seeing our data ( $X$ ) given our parameters ( $\theta$ ). This is written as  $p(X|\theta)$ .

In words, Bayes' theorem asserts that: The posterior probability of Event-1, given Event-2, is the product of the likelihood and the prior probability terms, divided by the evidence term.; In other words, you can use the corresponding values of the three terms on the right-hand side to get the posterior probability of an event, given another event.
